# Acknowledgements

- Supported by the Charles H. Hood Foundation; Maternal and Child Health Bureau HRSA (T71 MC 00009); NIH (NHLBI 1 K25 HL081275)

# Background: Childhood obesity is a significant public health problem

- Precipitous rise in prevalence across all sociodemographic groups
- Higher prevalence of obesity in:
  - African-American girls
  - Hispanic girls and boys
  - Low income girls and boys

## Background: School context likely influences student weight status

- Students spend many hours in school
- A large percentage of their daily intake is consumed at school
- Schools provide physical activity opportunities and/or requirements that influence overall physical activity levels
- Influence of teachers/role models and peers

# Background: Schools may contribute to racial/ethnic and/or socioeconomic disparities in weight status

- Schools have become increasingly segregated
- Differential availability of physical education
- Differential availability of vending machines and/or food and beverage advertising

# Study Aims

- To determine if there are school level differences in Body Mass Index (BMI) beyond that due to higher or lower risk students clustering in schools
- To determine if there are school level characteristics that predict individual level weight status

# National Longitudinal Study of Adolescent Health (Add Health)

- Nationally representative school-based study of adolescents in grades 7-12
- Schools were the primary sampling unit
- Sample: 17,007 adolescents in 132 schools

# Model Variables

- Outcome: Body Mass Index
  
- Individual level variables
  - Race/ethnicity
  - Age
  - Household income
  - Maternal education level
  
- School level variables
  - Racial/ethnic makeup of the student body
  - Median household income of school

# Statistical Analysis

- Cross-sectional analysis of Wave 1
- Gender-stratified, two-level random effects models
- School variance estimated before and after controlling for individual variables

# Individual and school characteristics by race/ethnicity

|  | White    | Black    | Hispanic | p-value          |
|--|----------|----------|----------|------------------|
| <b>Household income</b>                  | \$51,000 | \$30,000 | \$32,000 | <b>&lt;0.001</b> |
| <b>Maternal Education</b>                |          |          |          | <b>&lt;0.001</b> |
| No high school diploma                   | 8%       | 13%      | 38%      |                  |
| High school diploma +                    | 92%      | 87%      | 62%      |                  |
| <b>% White Students</b>                  |          |          |          | <b>&lt;0.001</b> |
| 1-66%                                    | 25%      | 80%      | 85%      |                  |
| 67-100%                                  | 75%      | 20%      | 15%      |                  |
| <b>Median Household Income of School</b> | \$45,000 | \$30,000 | \$32,500 | <b>&lt;0.001</b> |

# Body Mass Index by race/ethnicity

# What factors are associated with adolescent females' BMI?

| Two level random effects models clustered by school | + Individual Factors (beta) | + School Factors (beta) |

\* p<0.05

# Significant variation remains among school mean BMIs

■ Null ■ +Individual ■ +School

# Limitations

- Data collected in 1995
- Self-reported height and weight

# Conclusions

- Individual students attending schools with lower median household incomes had on average higher BMIs
- Significant *between* school variation in BMI exists even after accounting for the types of students attending different schools

# Public Health Implications

- Interventions at the school level may be able to reduce rates of obesity and may help to eliminate racial/ethnic and socioeconomic disparities in weight status
