# Purpose of the Research

To identify family demographic characteristics associated with high-risk vs. low-risk infant sleeping arrangements

# Background: Benefits and risks associated with bedsharing

- Benefits: facilitates breastfeeding and enhances parent-infant interactions
- Risks: increases chances for overheating, rebreathing CO<sub>2</sub> and exposure to tobacco smoke

Approximately half of all SIDS/SUDI in the US occur when the infant is bedsharing

# Roomsharing without bedsharing

- Growing body of evidence from multiple countries that roomsharing without bedsharing is protective against SIDS
- Possible mechanisms of protection: enhanced ability for parents to monitor the infant and increased infant arousal
- 2005: AAP recommended “separate but proximate sleep environment”—i.e. crib or bassinet in parent’s room

# Aim

To examine the maternal and infant characteristics associated with choice of infant sleeping arrangement, namely bedsharing vs. roomsharing without bedsharing vs. solitary sleeping\*

\* Note the change to looking at 3 (vs. 2) possible sleep locations

# Methods

- Face-to-face interviews conducted in 2005 with 708 mothers recruited from WIC
- Sites: Dallas, New Haven, Atlanta, Savannah
- Inclusion criteria: received WIC benefits, had an infant less than 8 months old, spoke English

# Statistical Analysis

- Means and SDs for continuous predictor variables
- Frequencies and percentages for categorical variables
- *Sleeping arrangement last night* as a 3-level outcome: 1) roomsharing without bedsharing; 2) bedsharing; 3) solitary sleeping
- Univariate analyses using ANOVA
- $P < 0.05$

# Statistical Analysis continued

- Multinomial logistic regression models for the 3-level outcome
  - Predictor variables entered simultaneously
  - Variables included if  $P \leq 0.1$  for 1 or 2 outcomes
  - Variables excluded if  $P > 0.1$  for 2 outcomes, except if exclusion increased SE of the remaining variables in the model
  - RRR, 95%CI calculated

# Results: Demographics

- 708 mothers included
  - Mean maternal age: 25 yo (SD=5.6)
  - Mean infant age: 4 mo (2.4)
  - Female infants: 51%
- % recruited from each site:  
23% (Savannah) - 27% (Dallas)

## Results: Univariate Analyses

| <HS                       | 0.43 (0.21, 0.91)*  |
| HS/GED                    | 0.45 (0.23, 0.88)*  |
| Some college              | 0.54 (0.27, 1.09)   |
| College/more              | 1                   |

# Summary of findings: Roomsharing without bedsharing

- The most common response in our population—about half of the infants
  - Study was conducted the same time the AAP recommendations were published
- More common for younger infants (vs. solitary sleeping)
  - Parents may be reluctant to leave younger infants in another room where monitoring is more difficult

# Summary: Bedsharing

- Still accounts for ~1/3 of our population
- More common among African Americans
  - May be 2-4x more common among AA vs. white infants (Unger 2003, Willinger 2003)
- More common with teenage mothers and mothers with less education, possible indicators of lower SES
  - More common with annual income <\$30,000 (Lahr 2006), teenage parent (McCoy 2004), if parent did not attend college (Brenner 2003)

# Possible rationales for bedsharing

- Economic
  - More common for lower SES
  - No funds to purchase or room for crib/bassinet
    - Free crib distribution programs needs testing
- Cultural norms
  - Hispanic vs. African-American
- Breastfeeding
  - Correlated in some studies & advocated by La Leche League
  - Recent study found SIDS risk caused by bedsharing not modified by breastfeeding

# Conclusion

- Bedsharing in a low-income population is associated with African-American race, having a teenage mother and lower maternal education
- All are also risk factors for SIDS
- Direction for future studies: Identify the reasons families with these demographic characteristics bedshare and identify interventions to change typical practices re. infant sleep location
