Presentation Outline

- Make the case for participation measurement
- Describe NIDRR-funded research that I have been involved in to measure participation
- Mention current NIH-funded efforts related to participation measurement
- Summarize conceptual and methodological issues in the measurement of participation

Why Measure Participation

- Participation is a key concept in the ICF
- Classification alone is not adequate to advance disability research
- Measures of ICF concepts are needed to determine the strengths of the arrows in the ICF
- Participation is the ICF outcome of greatest interest to people with disability, their families, and society
- Participation measurement is less advanced compared to impairment and activity measurement
- No consensus yet exists about how to measure participation

Participation Research in the NIDRR-funded Traumatic Brain Injury Model Systems

- Original TBIMS participation measure—Community Integration Measure (CIQ) had been scrapped due to poor psychometric properties
- A priority was placed on replacing the CIQ with a better measure of participation
- The developers of four other participation measures were Project Directors in the TBIMS
- They agreed to pool the items from the four measures in a collaborative study to determine which measure or new combination of items would form the best tool

Four TBIMS Participation Measures

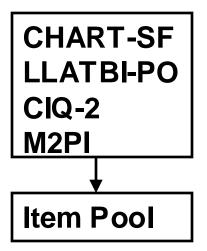

- Craig Handicap Assessment and Reporting Technique (CHART) Whiteneck et. al.
- The Participation Objective Subscale of Living Life After TBI (LLATBI-PO) Gordon et. al.
- The Community Integration Measure Version 2 (CIQ-2) Dijkers et. al.
- The Mayo Portland Participation Index (M2PI) Malec et. al.

PART-O

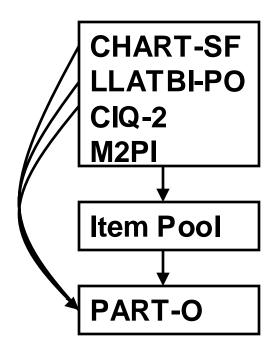

- Items selected from three of the four participation measures based on factor analysis, Rasch analysis, conceptual coverage yielded a superior measure
- Participation Assessed with Recombined Tools Objective (PART-O)
- Referred to as "objective" because all items sought relatively observable objective counts or frequencies of participation components (hours spent ..., number of..., times per month...)
- Criticized for judging participation based on societal norms

Participation Research in the NIDRR-funded RRTC on Rehabilitation Outcomes

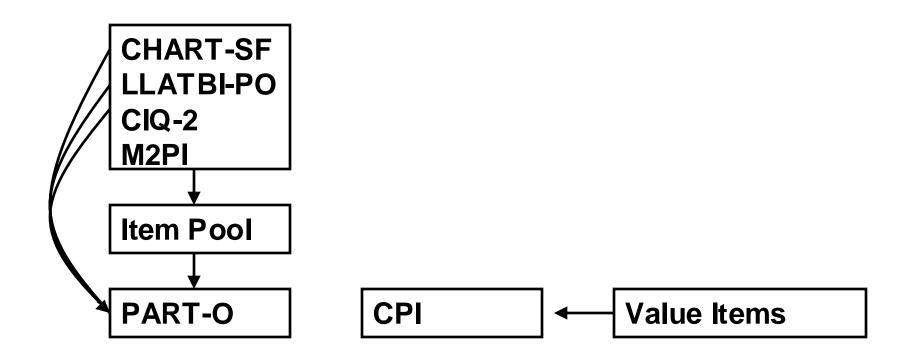

- Proposed to build a participation measure based on the perspectives of constituency groups
- Conducted 18 focus groups of 218 people with disability, their families and caregivers, service providers, insurance payors, and policy makers asking their view of participation
- Process yielded subjective "value items" addressing issues of choice and control, access and opportunity, meaningful engagement, inclusion, responsibilities, and having an impact
- These items formed the basis for a major section of the Community Participation Indicators (CPI) Heinemann et.al

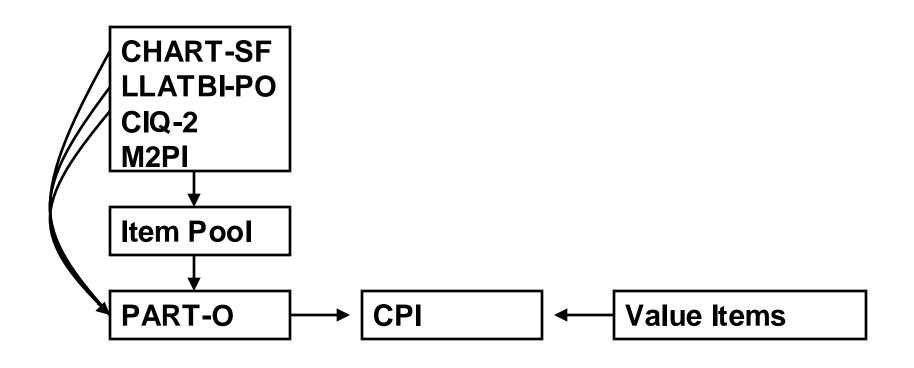

Value Items

Meanwhile Back at the TBIMS

- A second phase of research was undertaken to add a subjective component to the PART-O
- The Participation Subjective Subscale of the Living Life After TBI (LLATBI-PS) Gordon et. al. was used as the model for the subjective component in which people were asked to rate both the importance of, and their satisfaction with, participation domains
- The resulting tool was called PART-OSP (Objective, Subjective, and Perceptions)

Participation Research in the NIDRR-funded Spinal Cord Injury Model Systems

- In a strategy similar to the TBIMS, the SCIMS are testing a pool of items from five participation measures
- The CPI and PART-OSP have a majority of items in common and they start the item pool

Participation Research in the NIDRR-funded Spinal Cord Injury Model Systems

- Three additional measures were added to the pool representing other new participation measures
- A totally subjective measure was added with items of a similar nature to the CPI but containing different content—the Community Integration Measure (CIM) McColl et. al.
- The Participation Measure for Post Acute Care (PM-PAC) Jette et. al. was added addressing difficulty of participating
- Finally, the very objective Participation Profile (PAR-PRO) Granger et. al. was added

Participation Research Funded by NIH

- Two very large item banking efforts are underway at NIH designed to use computer adaptive testing
- The Patient Reported Outcomes Measurement Information System (PROMIS) includes two relevant item banks within the Social Health domain—Role Participation Limitations and Role Participation Satisfaction
- The Neurological Quality of Life Project (NeuroQual) includes two relevant item banks—Social Role Performance and Social Role Satisfaction

Key Conceptual Participation Issues

- Is participation unidimensional?
- Should a subjective dimension be included?
- Are there identifiable dimensions of objective participation?
- Initial evidence suggests three objective domains: Economic engagement (productivity) Micro-social engagement (family and friends) Macro-social engagement (community)
- And two subjective domains: Evaluation of engagement (satisfaction) Enfranchisement (extent individual is valued by society)

Key Methodological Participation Issues

- To what degree does participation meet the assumptions underlying modern psychometric theory and methods?
- Do individual preferences for selecting particular modes of participation (even within a domain) render analytic strategies such as item response theory and factor analysis less than ideal?
- Is a clinometric approach to measuring participation more appropriate than a psychometric approach?
- What item stems and responses will prove most effective? (frequency, satisfaction, difficulty, agreement)
