A Common Approach...

- Identify Locations and Frequencies of Collisions

- Identify Correlating Factors and Formulate Hypotheses

➤ Context of high frequency neighborhoods versus moderate and low frequency areas.

- Perform Regression Analysis and Evaluate Results

$$y_i = b_0 + b_1x_{i1} + b_2x_{i2} + \dots + b_kx_{ik} + e_i$$

WHERE:

y_i Frequency of collision

b_0 Estimate of numerical constant

b_k Numerical coefficients

x_{ik} Values of k independent variables

e_i Estimate of error (residual) in predicting frequency of collision

- Questions?

- Is this an appropriate investigation method into the spatial context of childhood pedestrian collisions?
- What problems may arise from using this method?
- What can be done to resolve these issues?

- Problem and Solution: Spatial Autocorrelation

- Problem: Grouping neighborhoods based on frequency of collision and neighborhood context begins to take the “space” out of a “spatial” analysis.

Problem Spots? Large number of collisions and large populations.

Problem Spots? Large number of collisions but small populations.

Ideal locations? Few collisions despite large populations.

- Solution: Taking underlying population values into account, identify adjacent locations (clusters) that have statistically significant high or low values.

- Problem and Solution: Spatial Autocorrelation

- Problem: The value of the dependent variable at one location can be impacted by the values of the independent variables at that location and at neighboring locations (spatial lag). The residuals across spatial units may also be autocorrelated (spatial error). These forms of spatial autocorrelation may lead to inflated coefficients and/or a better model fit.

$$y_i = b_0 + b_1x_{i1} + b_2x_{i2} + \dots + b_kx_{ik} + e_i$$

Inaccurate R²

Inflated

- Solution: First, detect any spatial lag or spatial error and then account for spatial autocorrelation in the regression analysis.

$$y_i = b_0 + b_1x_{i1} + b_2x_{i2} + \dots + b_kx_{ik} + e_i$$

Logit [Probability(Outcome)]

Add more variables

- ESDA and Childhood Pedestrian Collisions in Hartford, CT

- **ESDA**

- Exploratory spatial data analysis (ESDA) is a sophisticated method for detecting spatial patterns in data (clusters) meant for incorporation into statistical models.

- **Objective**

- Demonstrate the utility of ESDA in exploring the impact of specific variables on childhood pedestrian collisions in Hartford, CT.

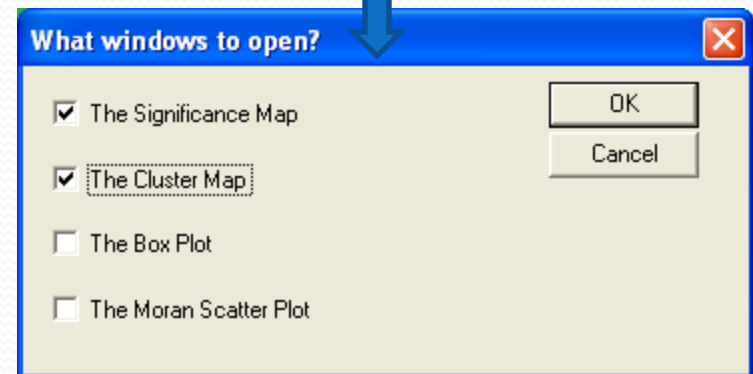

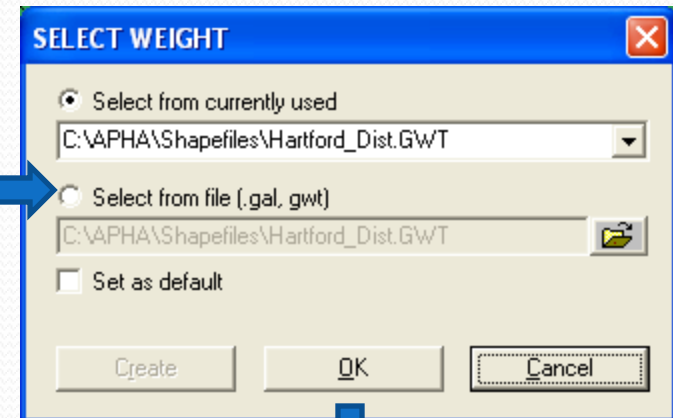

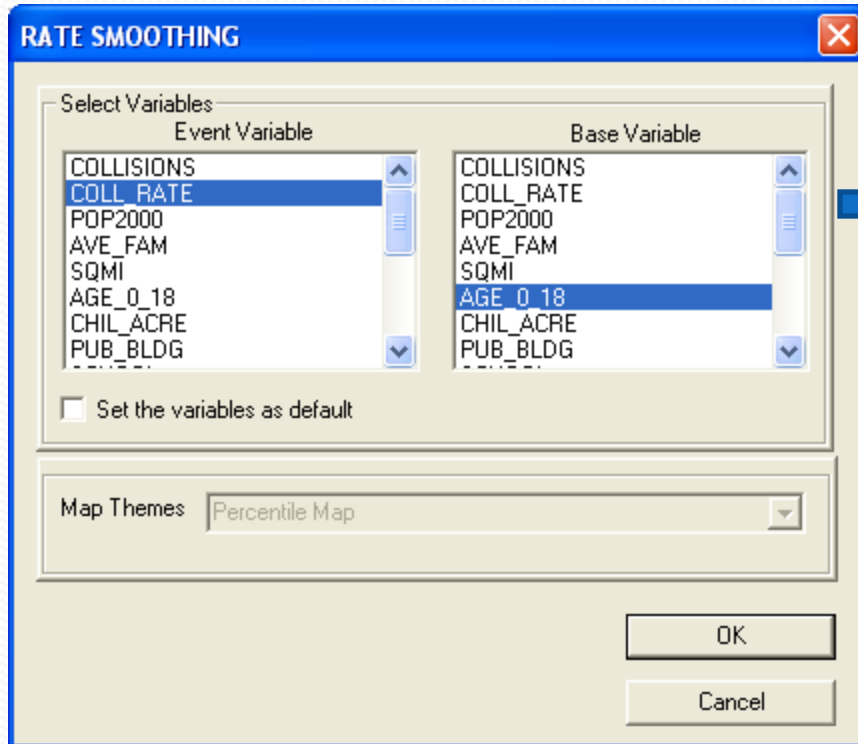

- **Data**

- **Dependent Variable:** frequency of childhood pedestrian collisions determined by Hartford census tract, 2005 – 2006.
- **Independent Variables:** contextual variables by census tract (poverty, education, schools, public buildings, housing characteristics, children per square mile).

- **Methods**

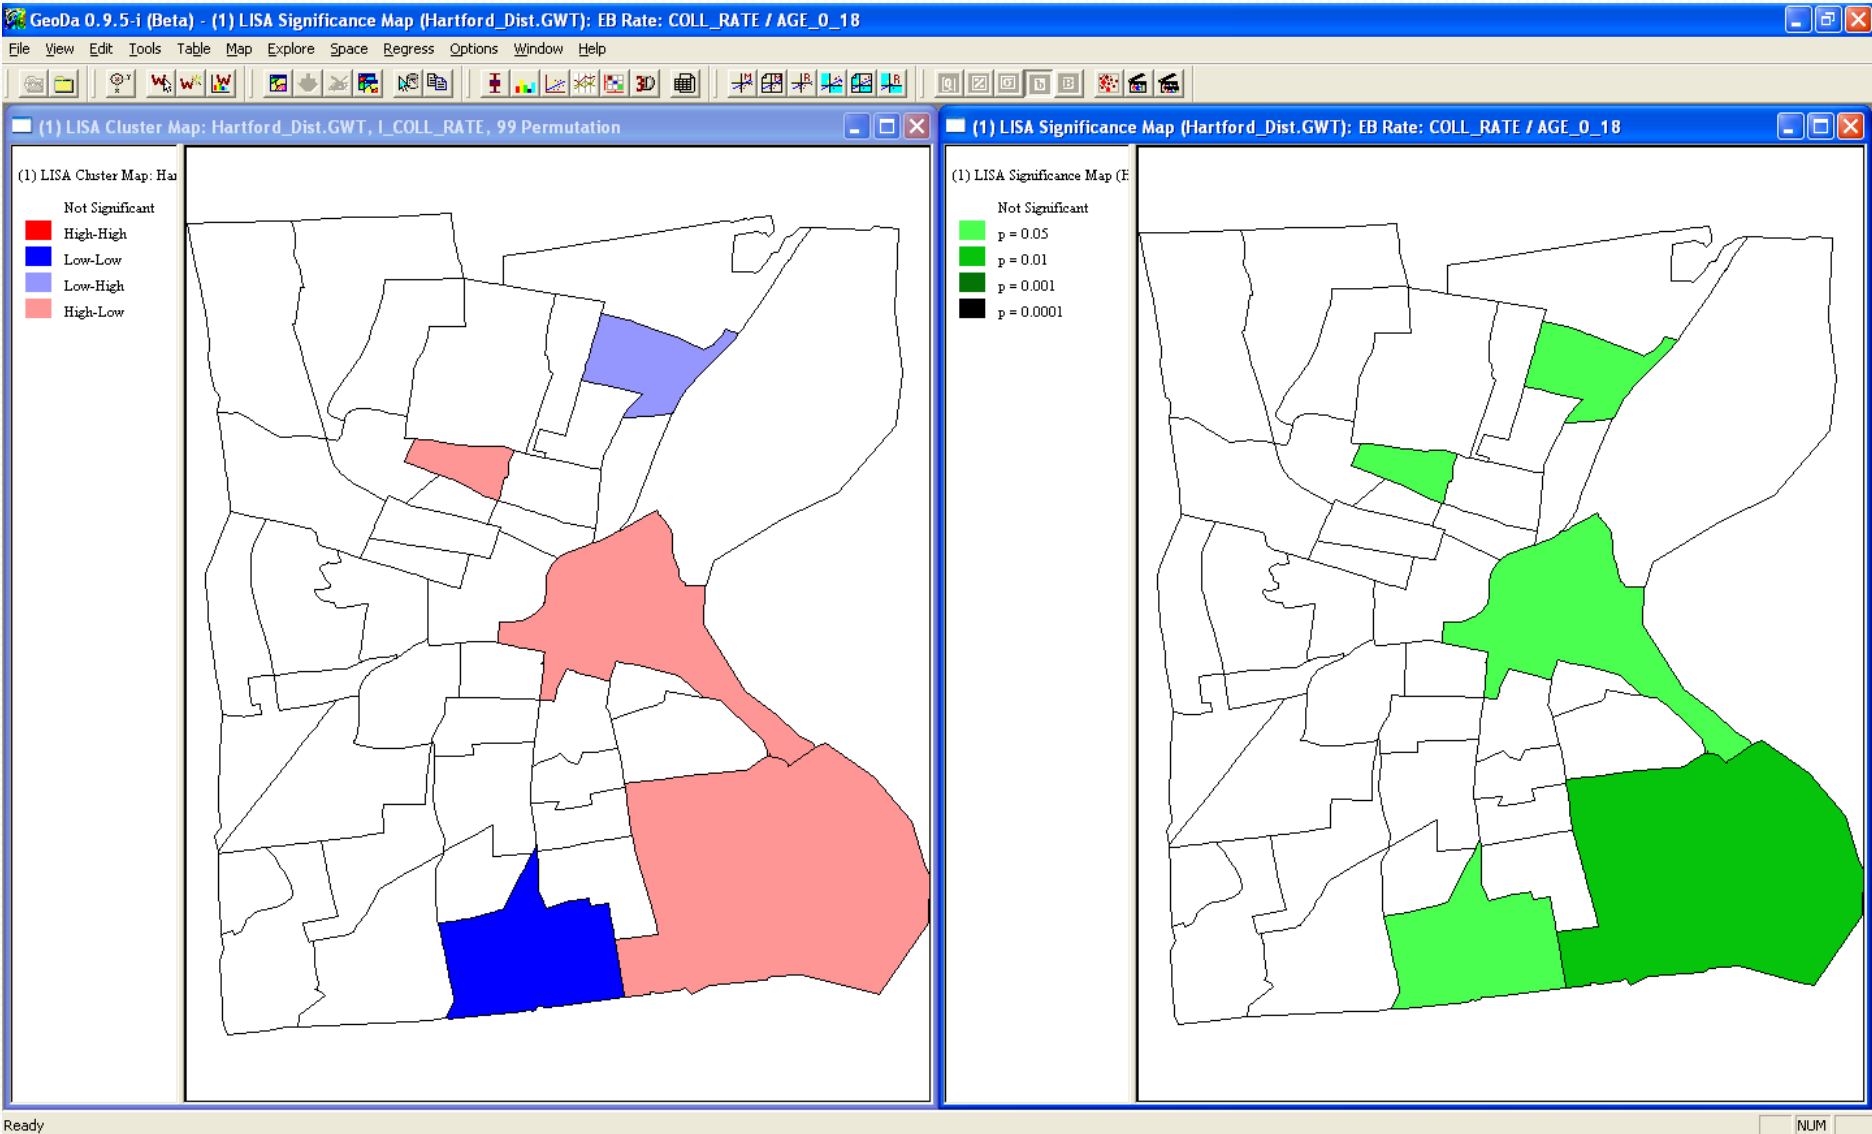

- Model statistically significant clusters using GeoDA.
- Perform regression analysis when accounting for spatial autocorrelation using GeoDA.

- ESDA and Childhood Pedestrian Collisions in Hartford, CT

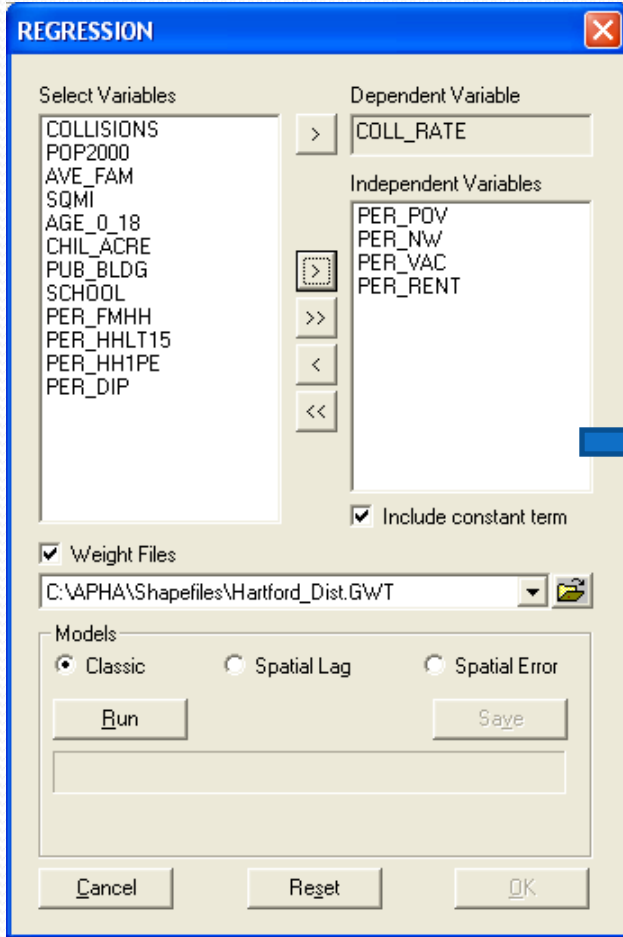

- Taking underlying population values into account, use a local indicator of spatial autocorrelation (LISA) to determine statistically significant clusters.

DIAGNOSTICS FOR SPATIAL DEPENDENCE

FOR WEIGHT MATRIX : Hartford_Dist.GWT (row-standardized weights)

TEST	MI/DF	VALUE	PROB
Moran's I (error)	0.072868	1.3474983	0.1778199
Lagrange Multiplier (lag)	1	0.5704315	0.4500875
Lagrange Multiplier (error)	1	0.3700903	0.5429550

- Perform regression analysis; diagnostics indicate no need to account for spatial autocorrelation.

- ESDA and Childhood Pedestrian Collisions in Hartford, CT

- Spatio-Temporal Analysis
 - ESDA could be used to investigate the changes in the number and location of high versus low clusters over time.
 - ESDA could be used to investigate the spatio-temporal characteristics of childhood pedestrian collisions, which has important ramifications for injury prevention.
- Conclusions
 - ESDA provides validity to spatial patterns using statistical significance.
 - ESDA provides a more robust examination of statistical relationships.
